Paradox of π ?

I wrote down the four paradoxes about love, measurement, solar eclipses and decoherence earlier today, while almost all ideas go back way longer. I have purposely left many things open in those earlier articles, in the hope to maybe spur the imagination of readers a bit more, and also because I might rather be interested in different things than pursuing them in the future.

My official take on this “fifth” paradox is that it is just wild speculation: Long-range “telepathic” connections with polarized spin 1 symmetry, passing unperturbed through any matter, mediated maybe by selective perception of virtual photons or the like? Unofficially, “eppur si muove”?

Such connections, especially between two lovers, would be felt most strongly if both persons would look into the direction of each other or into opposite directions, and gradually less strongly if not. Also, the feeling would be maximal if the symmetry planes of their heads would be aligned, e.g. if both were lying with their heads in the same direction or any opposite ones, and gradually weaker if not. The feeling would get weaker with more distance between the two, but apparently not decay quadratically with distance, and no matter in between, not even earth itself, would make a clear difference. The explanation might be that virtual photons, or maybe other spin 1 bosons, would mediate the felt connection, hence the symmetry of polarized light.
